

Trends in Antihypertensive-Associated Angioedema Reporting: A Narrative Review

K. Fernandez PharmD (1) | (1) Test School of Pharmacy

Abstract: This narrative review summarizes reporting trends for antihypertensive-associated angioedema across global pharmacovigilance databases over the past decade, without presenting a specific individual patient case. It is intended as background reading rather than a reportable case. (Fictional content created for software testing purposes.)

Introduction

Angioedema associated with antihypertensive therapy remains an area of active pharmacovigilance interest. This review aggregates published reporting rate trends without presenting a new individual case.

Reporting Trends

Aggregate spontaneous reporting data suggest a gradual increase in reported angioedema cases across several drug classes over the past decade, potentially reflecting both increased prescribing volumes and improved reporting awareness among clinicians.

Discussion

No single identifiable patient case is presented in this review; the discussion instead focuses on aggregate signal detection methodology and database-level trends, which is useful background but does not itself constitute an individual case safety report.

Conclusion

Continued aggregate surveillance, combined with individual case reporting, remains important for characterizing angioedema risk across antihypertensive classes.
