

Two Cases of Suspected Adverse Drug Reactions in Patients on Combination Antihypertensive-Antiepileptic Regimens

T. Alvarez MD (1), N. Rao MD (1) | (1) Dept. of Internal Medicine, Test Regional Hospital

Abstract: We present two distinct patient cases identified during a single clinic audit: one involving possible angioedema on amlodipine (Cardiozin), and a separate, unrelated patient with a breakthrough seizure while on Neurotab XR. Both cases are reported together due to shared identification during the same audit period. (Fictional cases, created for software testing purposes.)

Case 1

A 58-year-old woman on Cardiozin 10 mg daily for six weeks presented with mild lip swelling that resolved spontaneously within a few hours without treatment; she did not seek emergency care. The drug was continued at the treating physician's discretion after counseling on warning signs, with no recurrence over four weeks of follow-up.

Case 2

A 29-year-old man on Neurotab XR 200 mg twice daily for three months experienced a single breakthrough absence seizure during a period of reported poor sleep and medication non-adherence over the preceding week. Drug levels were not obtained. Symptoms did not recur after a period of improved adherence.

Discussion

These two unrelated cases, identified during the same institutional audit period, illustrate the range of severity and causality certainty encountered in routine adverse event surveillance, from self-limited reactions to escalation-associated events.

Conclusion

Both cases were considered independently reportable given the temporal association with suspect medications, despite differing severity and management pathways.
